- Finding projects

Learn how to contribute to a project through forking.

### Who can use this feature

Members of an enterprise with managed users cannot fork repositories from outside of the enterprise or fork internal repositories.

Mac Windows Linux

GitHub CLI Desktop Web browser

## About forking

If you want to contribute to someone else's project but don't have write access to the repository, you can use a "fork and pull request" workflow.

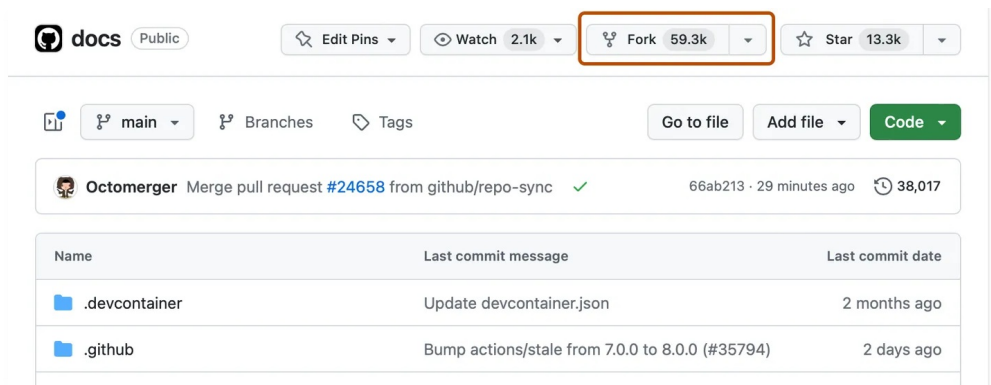

A fork is a new repository that shares code and visibility settings with the original "upstream" repository. Forks are often used to iterate on ideas or changes before they are proposed back to the upstream repository, such as in open source projects or when a user does not have write access to the upstream repository.

You can contribute by submitting pull requests from your fork to the upstream repository. For more information, see "[Fork a repo](#)."

## Forking a repository

This tutorial uses [the Spoon-Knife project](#), a test repository that's hosted on GitHub.com that lets you test the fork and pull request workflow.

- 1 Navigate to the `Spoon-Knife` project at <https://github.com/octocat/Spoon-Knife>.
- 2 In the top-right corner of the page, click **Fork**.

- Under "Owner," select the dropdown menu and click an owner for the forked repository.
- By default, forks are named the same as their upstream repositories. Optionally, to further distinguish your fork, in the "Repository name" field, type a name.
- Optionally, in the "Description" field, type a description of your fork.
- Optionally, select **Copy the DEFAULT branch only**.

For many forking scenarios, such as contributing to open-source projects, you only need to copy the default branch. If you do not select this option, all branches will be copied into the new fork.

- Click **Create fork**.

**Note:** If you want to copy additional branches from the upstream repository, you can do so from the **Branches** page. For more information, see "[Creating and deleting branches within your repository](#)."

## Cloning a fork

You've successfully forked the Spoon-Knife repository, but so far, it only exists on GitHub Enterprise Cloud. To be able to work on the project, you will need to clone it to your computer.

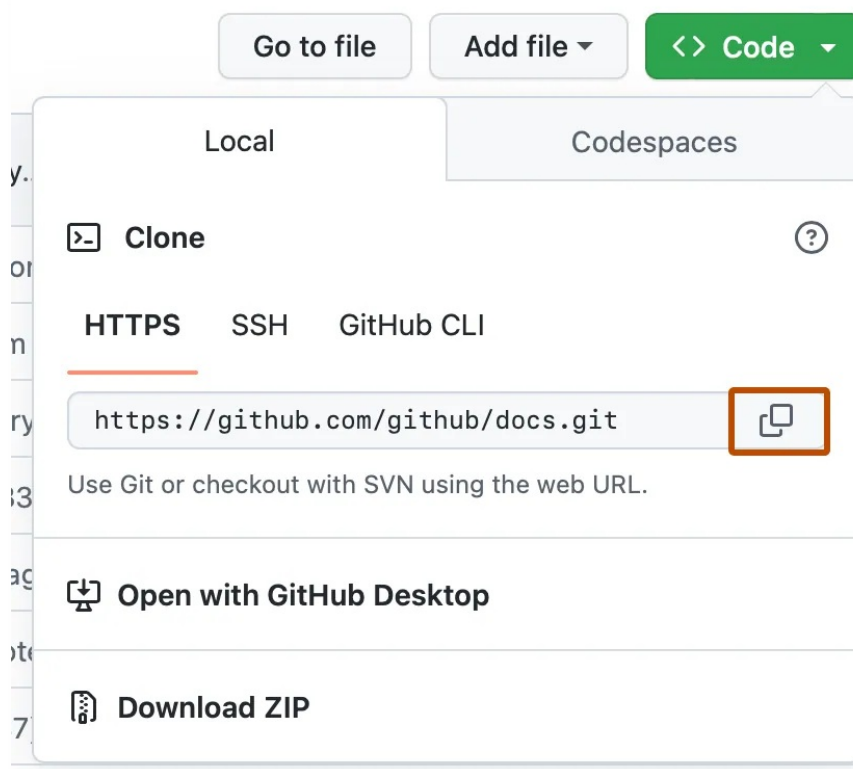

You can clone your fork with the command line, GitHub CLI, or GitHub Desktop.

- On GitHub Enterprise Cloud, navigate to **your fork** of the Spoon-Knife repository.
- Above the list of files, click <> **Code**.

3 Copy the URL for the repository.

- To clone the repository using HTTPS, under "HTTPS", click .
- To clone the repository using an SSH key, including a certificate issued by your organization's SSH certificate authority, click **SSH**, then click .
- To clone a repository using GitHub CLI, click **GitHub CLI**, then click .

4 Open TerminalTerminalGit Bash.

5 Change the current working directory to the location where you want the cloned directory.

6 Type `git clone`, and then paste the URL you copied earlier. It will look like this, with your GitHub Enterprise Cloud username instead of `YOUR-USERNAME`:

```
git clone https://github.com/YOUR-USERNAME/Spoon-Knife
```

- 7 Press **Enter**. Your local clone will be created.

```
$ git clone https://github.com/YOUR-USERNAME/Spoon-Knife
> Cloning into `Spoon-Knife`...
> remote: Counting objects: 10, done.
> remote: Compressing objects: 100% (8/8), done.
> remove: Total 10 (delta 1), reused 10 (delta 1)
> Unpacking objects: 100% (10/10), done.
```

To learn more about GitHub CLI, see "[About GitHub CLI](#)."

To create a clone of your fork, use the `--clone` flag.

```
gh repo fork REPOSITORY --clone=true
```

- 1 In the **File** menu, click **Clone Repository**.

- 2 Click the tab that corresponds to the location of the repository you want to clone. You can also click **URL** to manually enter the repository location.

- 3 From the list of repositories, click the repository you want to clone.

- 4 To select the local directory into which you want to clone the repository, next to the "Local Path" field, click **Choose...** and navigate to the directory.

- 5 At the bottom of the "Clone a Repository" window, click **Clone**.

## Creating a branch to work on [🔗](#)

Before making changes to the project, you should create a new branch and check it out. By keeping changes in their own branch, you follow GitHub Flow and ensure that it will be easier to contribute to the same project again in the future. For more information, see "[GitHub flow](#)."

```
git branch BRANCH-NAME
git checkout BRANCH-NAME
```

```
git branch BRANCH-NAME
git checkout BRANCH-NAME
```

For more information about how to create and manage branches in GitHub Desktop, see "[Managing branches in GitHub Desktop](#)."

## Making and pushing changes [🔗](#)

Go ahead and make a few changes to the project using your favorite text editor, like [Visual Studio Code](#). You could, for example, change the text in `index.html` to add your GitHub username.

When you're ready to submit your changes, stage and commit your changes. `git add .` tells Git that you want to include all of your changes in the next commit. `git commit` takes a snapshot of those changes.

```
git add .
git commit -m "a short description of the change"
```

```
git add .
git commit -m "a short description of the change"
```

For more information about how to stage and commit changes in GitHub Desktop, see "[Committing and reviewing changes to your project in GitHub Desktop](#)."

When you stage and commit files, you essentially tell Git, "Okay, take a snapshot of my changes!" You can continue to make more changes, and take more commit snapshots.

Right now, your changes only exist locally. When you're ready to push your changes up to GitHub Enterprise Cloud, push your changes to the remote.

```
git push
```

```
git push
```

For more information about how to push changes in GitHub Desktop, see "[Pushing changes to GitHub from GitHub Desktop](#)."

## Making a pull request

At last, you're ready to propose changes into the main project! This is the final step in producing a fork of someone else's project, and arguably the most important. If you've made a change that you feel would benefit the community as a whole, you should definitely consider contributing back.

To do so, head on over to the repository on GitHub Enterprise Cloud where your project lives. For this example, it would be at `https://github.com/<your_username>/Spoon-Knife`. You'll see a banner indicating that your branch is one commit ahead of `octocat:main`. Click **Contribute** and then **Open a pull request**.

GitHub Enterprise Cloud will bring you to a page that shows the differences between your fork and the `octocat/Spoon-Knife` repository. Click **Create pull request**.

GitHub Enterprise Cloud will bring you to a page where you can enter a title and a description of your changes. It's important to provide as much useful information and a rationale for why you're making this pull request in the first place. The project owner needs to be able to determine whether your change is as useful to everyone as you think it is. Finally, click **Create pull request**.

## Managing feedback

Pull Requests are an area for discussion. In this case, the Octocat is very busy, and probably won't merge your changes. For other projects, don't be offended if the project owner rejects your pull request, or asks for more information on why it's been made. It may even be that the project owner chooses not to merge your pull request, and that's totally okay. Your changes exist in your fork. And who knows--maybe someone you've never met will find your changes much more valuable than the original project.

## Finding projects

You've successfully forked and contributed back to a repository. Go forth, and contribute some more!
